

## LEAN 4 CHEATSHEET

If a tactic is not recognized, write `import Mathlib.Tactic` at the top of your file.

Logical symbol	Appears in goal	Appears in hypothesis
$\forall$ (for all)	<code>intro x</code>	<code>apply h</code> or <code>specialize h x</code>
$\rightarrow$ (implies)	<code>intro h</code>	<code>apply h</code> or <code>specialize h1 h2</code>
$\neg$ (not)	<code>intro h</code>	<code>apply h</code> or <code>contradiction</code>
$\leftrightarrow$ (if and only if)	<code>constructor</code>	<code>rw [h]</code> or <code>rw [← h]</code> or <code>apply h.1</code> or <code>apply h.2</code>
$\wedge$ (and)	<code>constructor</code>	<code>obtain ⟨h1, h2⟩ := h</code>
$\exists$ (there exists)	<code>use x</code>	<code>obtain ⟨x, hx⟩ := h</code>
$\vee$ (or)	<code>left</code> or <code>right</code>	<code>obtain h1 h2 := h</code>
$a = b$ (equality)	<code>rfl</code> or <code>ext</code>	<code>rw [h]</code> or <code>rw [← h]</code>
True	<code>trivial</code>	—
False	—	<code>contradiction</code>

Tactic	Effect
<b>Applying Lemmas</b>	
<code>exact <i>expr</i></code>	prove the current goal exactly by <i>expr</i> .
<code>apply <i>expr</i></code>	prove the current goal by applying <i>expr</i> to some arguments.
<code>refine <i>expr</i></code>	like <code>exact</code> , but <i>expr</i> can contain <code>?_</code> that will be turned into a new goal.
<code>convert <i>expr</i></code>	prove the goal by showing that it is equal to the type of <i>expr</i> .
<b>Context manipulation</b>	
<code>have h : <i>proposition</i> := <i>expr</i></code>	add a new hypothesis <b>h</b> of type <i>proposition</i> . <b>▲ Do not use for data!</b>
<code>have h : <i>proposition</i> := by</code>	add hypothesis <b>h</b> after proving it using tactics. <b>▲ Do not use for data!</b>
<code>set x : <i>type</i> := <i>expr</i></code>	add an abbreviation <b>x</b> with value <i>expr</i> .
<code>clear h</code>	remove hypothesis <b>h</b> from the context.
<code>rename_i x h</code>	rename the last inaccessible names with the given names.
<code>show <i>expr</i></code>	Replaces the goal by <i>expr</i> , if they are equal by definition.
<b>Rewriting and simplifying</b>	
<code>rw [<i>expr</i>]</code>	in the goal, replace (all occurrences of) the left-hand side of <i>expr</i> by its right-hand side. <i>expr</i> must be an equality, iff statement or definition.
<code>rw [←<i>expr</i>]</code>	... rewrites using <i>expr</i> from right-to-left.
<code>rw [<i>expr</i>] at h</code>	... rewrite in hypothesis <b>h</b> .
<code>nth_rw n [<i>expr</i>]</code>	rewrite only the <i>n</i> -th occurrence of the rewrite rule <i>expr</i> .
<code>simp</code>	simplify the goal using all lemmas tagged <code>@[simp]</code> and basic reductions.
<code>simp at h</code>	... simplify in hypothesis <b>h</b> .
<code>simp [*, <i>expr</i>]</code>	... also simplify with all hypotheses and <i>expr</i> .
<code>simp only [<i>expr</i>]</code>	... only simplify with <i>expr</i> and basic reductions (not with simp-lemmas).
<code>simp?</code>	... let Lean speed up <code>simp</code> by specifying which lemmas were used.
<code>simp_rw [<i>expr1</i>, ...]</code>	like <code>rw</code> , but uses <code>simp only</code> at each step.
<code>simp_all</code>	repeatedly simplify the goal and all hypothesis using all hypotheses.
<code>norm_num</code>	simplify numerical expressions by calculating.
<code>norm_cast</code>	simplify the expression by moving casts ( $\uparrow$ ) outwards.
<code>push_cast</code>	push casts inwards.
<code>conv =&gt; <i>conv-tac</i></code>	apply rewrite rules to only part of the goal. Use <code>congr</code> , <code>skip</code> , <code>ext</code> , <code>lhs</code> , <code>rhs</code> , ... to navigate to the desired subexpression. See TPIL.
<code>split_ifs</code>	case split on every occurrence of <code>if h then <i>expr</i> else <i>expr</i></code> in the goal.

<code>calc a = b := by tac</code> <code>  _ ≤ c := by tac</code> <code>  _ &lt; d := by tac</code> <code>rfl</code> <code>symm</code> <code>trans expr</code> <code>subst h</code> <code>ext</code> <code>apply_fun expr at h</code> <code>linear_combination</code> <code>congr</code> <code>gcongr</code> <code>positivity</code> <code>bound</code> <code>omega</code> <code>linarith</code> <code>nlinarith</code>	<b>Reasoning with equalities, inequalities, and other relations</b> perform a calculation 💡 after writing “ <code>calc _</code> ” Lean can generate a basic <code>calc</code> -block for you. 💡 after a <code>by</code> shift-click on a subterm in the goal to create a new step. prove the current goal by reflexivity. swap a symmetric relation. split a transitive relation into two parts with <code>expr</code> in the middle. if <code>h</code> equates a variable with a value, substitute the value for the variable. prove an equality in a specified type (e.g. functions). apply <code>expr</code> to both sides of the (in)equality <code>h</code> . prove an equality by specifying it as a linear combination of hypotheses. prove an equality using congruence rules. prove an inequality using congruence rules. prove goals of the form $0 < x$ , $0 \leq x$ and $x \neq 0$ . prove inequalities based on the expression structure. solve linear arithmetic problems over $\mathbb{N}$ or $\mathbb{Z}$ . prove linear (in)equalities from the hypotheses. stronger variant of <code>linarith</code> that can solve some nonlinear inequalities.
<code>ex falso</code> <code>by_contra h</code> <code>push_neg or push_neg at h</code> <code>by_cases h : proposition</code> <code>choose f h using expr</code> <code>lift n to type using h</code> <code>zify / qify / rify</code> <code>induction n with</code> <code>    zero =&gt; tac</code> <code>    succ n ih =&gt; tac</code>	<b>Reasoning techniques</b> replace the current goal by <code>False</code> . proof by contradiction; adds the negation of the goal as hypothesis <code>h</code> . push negations into quantifiers and connectives in the goal (or in <code>h</code> ). case-split on <code>proposition</code> . extract a function from a forall-exists statement <code>expr</code> . lifts a variable to <code>type</code> (e.g. $\mathbb{N}$ ) using side-condition <code>h</code> . shift an (in)equality to $\mathbb{Z}$ / $\mathbb{Q}$ / $\mathbb{R}$ . prove a goal by induction on <code>n</code> .  💡 after writing “ <code>induction n</code> ” Lean can generate the cases for you.
<code>exact?</code> <code>apply?</code> <code>rw?</code> <code>have? using h1, h2</code> <code>hint</code>	<b>Searching</b> search for a single lemma that closes the goal using the current hypotheses. gives a list of lemmas that can apply to the current goal. gives a list of lemmas that can be used to rewrite the current goal. try to find facts that can be concluded by using both <code>h1</code> and <code>h2</code> . run a few common tactics on the goal, reporting which one succeeded.
<code>ring / noncomm_ring / module</code> <code>field_simp / abel / group</code> <code>aesop</code> <code>tauto</code> <code>decide</code>	<b>General automation</b> prove the goal by using the axioms of a commutative ring / ring / module / field / abelian group / group. simplify the goal, and use various techniques to prove the goal. prove logical tautologies. run a decision procedure to prove the goal (if it is decidable).
<code>swap</code> <code>pick_goal n</code> <code>all_goals tac</code> <code>try tac</code> <code>sorry</code>	<b>Misc</b> swap the first two goals. move goal <code>n</code> to the front. apply <code>tac</code> to all goals. apply <code>tac</code> only if it succeeds. admit the current goal.

### Domain-specific tactics

<code>fin_cases h</code>	split a hypothesis <code>h</code> into finitely many cases.
<code>interval_cases n</code>	if split the goal into cases for each of the possible values for <code>n</code> .
<code>compute_degree</code>	prove (in)equalities about the degree of a polynomial
<code>monicity</code>	prove that a polynomial is monic
<code>fun_prop</code>	prove that a function satisfies a property (continuity, measurability, ...).
<code>measurability</code>	prove that a set or function is measurable.
<code>filter_upwards [h1, h2]</code>	Show that an <b>Eventually</b> goal follows from the given hypotheses.

---

### Legend

- 💡 describes a code action for this tactic.
- 🌐 requires internet access.

### Usage note

This is a quick overview of the most common tactics in Lean with only a short description. To learn more about a tactic or learn its precise syntax or variants, consult its docstring. You can use `#help tactic tac` to find the full syntax, variants and more information about `tac`. Use `#help tactic` to list all imported tactics.

### Some useful commands

Some commands also work as tactics!

<code>#loogle query</code>	🌐 use Loogle! to find declarations.
<code>#leansearch "query."</code>	🌐 use LeanSearch to find declarations.
<code>#exit</code>	don't compile code after this command.
<code>#lint</code>	run linters to find common mistakes in the code <i>above</i> this command.
<code>#where</code>	print current opened namespaces, universes, variables and options.
<code>#help tactic tac</code>	find information about <code>tac</code> .
<code>#help category</code>	list all tactics/commands/attributes/options/notations.
